US ERA ARCHIVE DOCUMENT

# Formation of Secondary Organic Aerosol

John H. Seinfeld
California Institute of Technology
STAR Grant Meeting
May 7, 2008

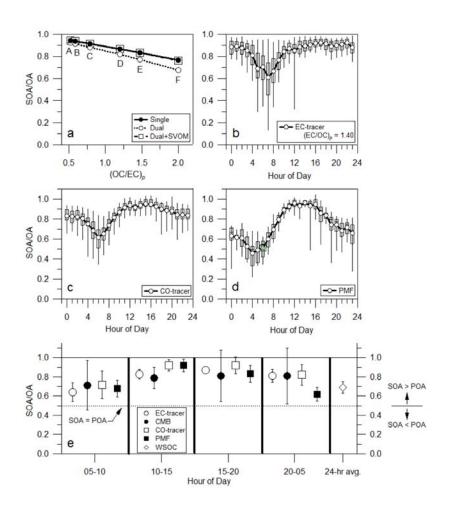

### Conundrums

- Radiocarbon (<sup>14</sup>C) data consistently indicate that well over half of ambient SOA is of modern (biogenic) origin.
- Field measurements show correlation between WSOC (or AMS OOA spectra) and anthropogenic tracers, such as CO, suggesting that much of ambient SOA is of anthropogenic origin.
- Comparisons between ambient measured SOA and that predicted based on known precursors suggest that there is a substantial amount of "missing carbon" not in current models [De Gouw et al., 2005; Volkamer et al., 2006].

Table 5. Global SOA budgets.

Hydrocarbon	Emission (Tg/yr)	SOA Production (Tg/yr)	Burden (Tg)
terpenes	121	8.2	0.21
alcohols	38.3	1.5	0.03
sesquiterpenes	14.8	2.0	0.03
isoprene	461	13.2	0.43
aromatics	18.8	3.5	0.08
total	654	28.4	0.78

Henze, D.K. et al., Global modeling of secondary organic aerosol formation from aromatic hydrocarbons: high vs. low yield pathways, *Atmos. Chem. Phys.*, in press.

# Secondary Organic Aerosol: Predictions versus Observations

Possible reasons for discrepancy between predictions and observations:

- 1. Ambient SOA yields for those parent hydrocarbons known to produce SOA exceed those measured in laboratory chambers.
- 2. Classes of SOA-forming organics exist that have yet to be studied in the laboratory or included in atmospheric models.
- 3. Uncertainties in current treatments of SOA formation in global models lead to biases that result in underpredictions.

1. Ambient SOA yields for those parent hydrocarbons known to produce SOA exceed those measured in laboratory chambers.

- SOA yields determined in laboratory chambers until recently were not fully controlled for NO<sub>x</sub> level.
- For isoprene, monoterpenes, and aromatics, SOA yields increase strongly as NO<sub>x</sub> decreases toward non-urban levels.
- For sesquiterpenes, SOA yields increase as NO<sub>x</sub> increases, owing to formation of nitrate-containing products and/or efficient isomerization of alkoxy radicals to form relatively nonvolatile products (Ng et al., 2007).\*

<sup>\*</sup> Ng, N. L. et al., Effect of  $NO_x$  level on secondary organic aerosol (SOA) formation from the photooxidation of terpenes, *ACP*, 2007.

- 2. Classes of SOA forming organics exist that have yet to be studied in the laboratory or included in atmospheric models.
  - At present, biogenic VOCs, isoprene and the terpenes, are considered as the dominant global sources of SOA.
  - Aromatic SOA production has been re-evaluated (Ng et al., 2007)\* and contribution can be appreciable at the urban/regional scale.
  - Robinson et al. (Science, 2007): The gas-phase component of primary semivolatile OA emissions can be photooxidized to lead to SOA. This source of SOA is potentially significant.
  - Potential of both larger, e.g. diesel hydrocarbons, and smaller molecules, e.g. acetylene, to serve as parent VOCs?

<sup>\*</sup>Ng, N. L. et al., Secondary organic aerosol formation from *m*-xylene, toluene, and benzene, *ACP*, **7**, 3909-3922 (2007)

 Uncertainties in current treatments of SOA formation in global models lead to biases that result in underpredictions.

- Updating of SOA yields to account for NO<sub>x</sub> dependence, aerosol acidity, RH (Henze et al., 2007)\*
- Addition of VOCs not currently considered as SOA sources, e.g. primary semivolatile VOCs
- Effect of SOA volatility (V.P., ΔH<sub>v</sub>) uncertain: ΔH<sub>v</sub> estimates in current models range from 156 kJ/mol to 42 kJ/mol

<sup>\*</sup>Henze, D. K. et al., Global modeling of secondary organic aerosol from aromatic hydrocarbons: High- vs. low-yield pathways, *ACP*, in press.

### Goals of Caltech Project

- To continue to elucidate the mechanisms of formation and SOA yields of all important classes of atmospheric hydrocarbons (to attempt to understand discrepancy between observed and modeled ambient SOA levels).
- To develop a "next-generation" SOA model, constrained by laboratory data, for inclusion in chemical transport and general circulation models. Model should account for:

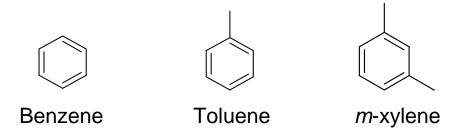

Effects of NO<sub>x</sub> level on mechanisms

Evolution of volatility of oxidation products

Particle-phase chemistry

#### **Aromatic SOA**

 Study systematically the effect of NO<sub>x</sub> on SOA formation from selected aromatic hydrocarbons

- Obtain SOA yields at high- and low-NO<sub>x</sub> conditions (the limiting cases), parameterize the NO<sub>x</sub> dependence for modeling purposes
- Investigate the effect of particle phase acidity on aerosol growth

### Growth curves: m-xylene

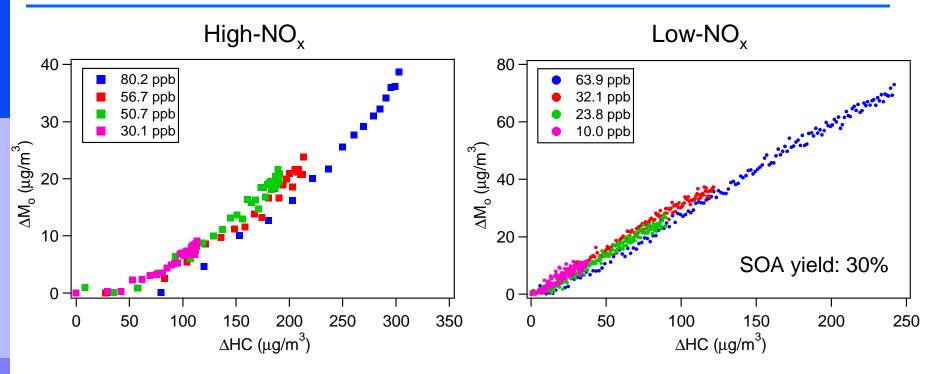

- High-NO<sub>x</sub>: Growth curves do not overlap, multiple rate-limiting steps in SOA formation (first step is the slowest)
- Further-generation oxidation products

- SOA yields much higher than high-NO<sub>x</sub> experiments
- Constant SOA yield implies essentially nonvolatile oxidation products (36% yield)

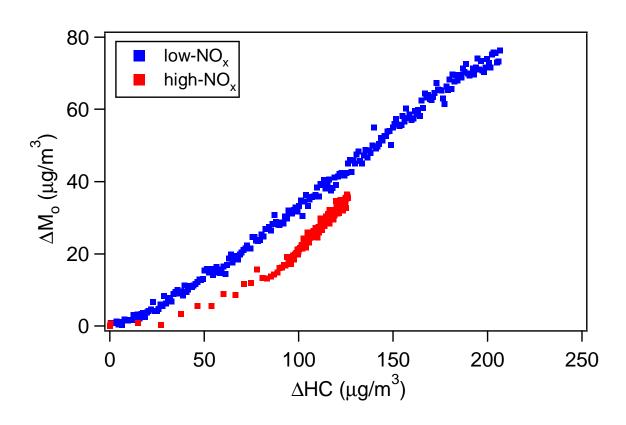

### Growth curves: toluene

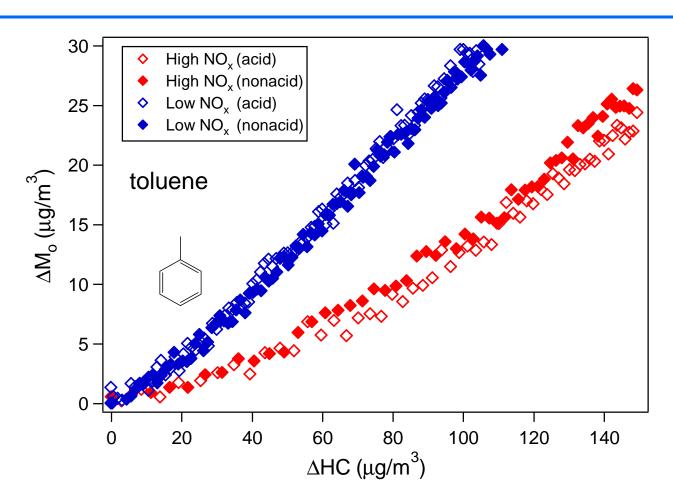

#### Growth curves: benzene

- ~400 ppb benzene (slow reaction rate, <20% reacted)
- Same NO<sub>x</sub> dependence as *m*-xylene and toluene: high NO<sub>x</sub>, lower yields
- Low NO<sub>x</sub>: constant yield of 37%

### Seed acidity: acid seed vs. non-acid seed

- No acid effect observed
- Same observations in *m*-xylene oxidation

### Effect of Acidity on Hydrocarbons Studied at Caltech

Parent	т	RH						
Hydrocarbon	(K)	(%)	Oxidant	NO <sub>x</sub> Condition	Seed Type	∆HC (ppb)	$\Delta M_o (\mu g/m^3)$	SOA Yield (%)
α-pinene	293	55	O <sub>3</sub>	n/a	neutral	12	20.4	30.1
$\alpha$ -pinene	293	55	O <sub>3</sub>	n/a	highly acidic	12	28.0	41.3
isoprene	297	~9	OH radical	Low-NO <sub>x</sub>	neutral	500	73	5.2
isoprene	297	~9	OH radical	Low-NO <sub>x</sub>	acidic	500	259	18.5
<i>m</i> -xylene	297	5.0	OH radical	High-NO <sub>x</sub>	neutral	68.9	78.9	26.3
<i>m</i> -xylene	298	4.2	OH radical	High-NO <sub>x</sub>	acidic	68.5	78.3	26.3
<i>m</i> -xylene	297	4.3	OH radical	Low-NO <sub>x</sub>	neutral	60.2	101.3	38.6
<i>m</i> -xylene	297	4.5	OH radical	Low-NO <sub>x</sub>	acidic	58.8	103.5	40.4
toluene	296	4.9	OH radical	High-NO <sub>x</sub>	neutral	60.0	43.8	19.3
toluene	298	4.9	OH radical	High-NO <sub>x</sub>	acidic	58.2	38.4	17.4
toluene	298	5.9	OH radical	Low-NO <sub>x</sub>	neutral	37.9	41.0	38.7
toluene	299	4.6	OH radical	Low-NO <sub>x</sub>	acidic	38.9	43.2	29.5

no
enhancements

increasing
aerosol acidity

neutral = 15 mM (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> acidic = 15 mM (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> + 15 mM H<sub>2</sub>SO<sub>4</sub> highly acidic = 30 mM (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> + 50 mM H<sub>2</sub>SO<sub>4</sub>

• Currently, only enhancements in biogenic SOA have been observed with increasing aerosol acidity - consistent with composition data (i.e. organosulfates)

Aromatic oxidized by OH to form peroxy radical (assumed only product)

$$AROM + OH \rightarrow ARO_2$$

HO<sub>2</sub> and NO compete for ARO<sub>2</sub>

$$ARO_2 + HO_2 \rightarrow \alpha_H SOG_H$$

$$ARO_2 + NO \rightarrow \alpha_{N,1}SOG_{N,1} + \alpha_{N,2}SOG_{N,2}$$

Aromatic oxidized by OH to form peroxy radical (assumed only product)

$$AROM + OH \rightarrow ARO_2$$

HO<sub>2</sub> and NO compete for ARO<sub>2</sub>

$$ARO_2 + HO_2 \rightarrow \alpha_H SOG_H$$

**SOA** Partitioning:

$$SOAa$$
 $|_{K_{N,1}}$ 
 $|_{K_{N,2}}$ 

$$ARO_2 + NO \rightarrow \alpha_{N,1}SOG_{N,1} + \alpha_{N,2}SOG_{N,2}$$

Aromatic oxidized by OH to form peroxy radical (assumed only product)

$$AROM + OH \rightarrow ARO_2$$

HO<sub>2</sub> and NO compete for ARO<sub>2</sub>

$$ARO_2 + HO_2 \rightarrow \alpha_H SOG_H$$

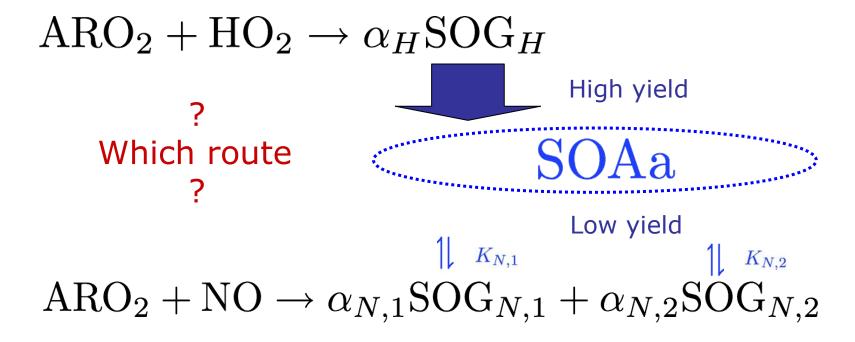

SOA Partitioning:

Aromatic oxidized by OH to form peroxy radical (assumed only product)

$$AROM + OH \rightarrow ARO_2$$

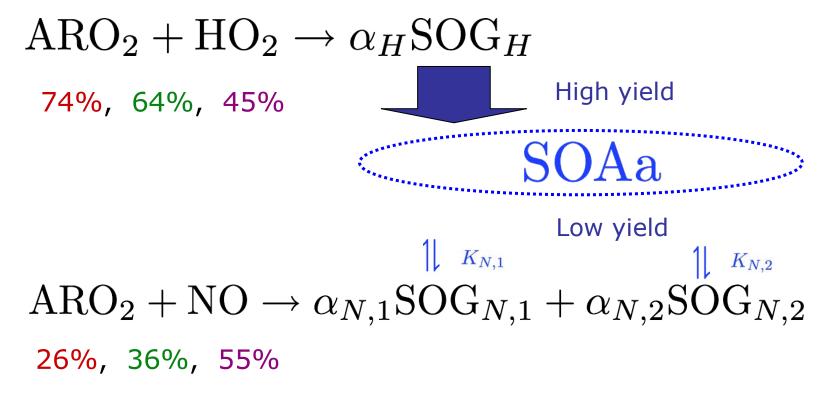

HO<sub>2</sub> and NO compete for ARO<sub>2</sub>

### Anthropogenic SOA Formation Pathways

Dominant pathway depends upon aromatic

Benzene, Toluene, Xylene

Less reactive aromatics --> more SOA

### Anthropogenic SOA Formation Pathways

Total from all sources

90% of SOAa comes from low NO<sub>x</sub> pathway

### Observations on NO<sub>X</sub> Dependence

- In summary, isoprene shown to have lower SOA yields under high-NO<sub>x</sub> conditions and seems to be consistent with our understanding of RO<sub>2</sub> chemistry
- Monoterpenes (C<sub>10</sub>H<sub>16</sub>) and aromatic VOCs found to have same NO<sub>x</sub> dependence on SOA formation as isoprene (i.e. higher SOA yields under low- NO<sub>x</sub> conditions) [Ng et al., ACP, 2007ab]
- Larger VOCs, such as sesquiterpenes (C<sub>15</sub>H<sub>24</sub>) and large alkanes (> C<sub>10</sub>), have been shown to produce higher SOA yields under high-NOx conditions [Ng et al., ACP, 2007a; Lim et al., ES&T, 2005]
- Chemical compositions of monoterpenes and aromatic VOCs need to be fully characterized, as this may provide further insights as to why SOA yields are higher at low-NO<sub>x</sub> conditions
- Fully and accurately characterizing NOx dependences of all SOA precursors will likely help to close gap between modeled and observed SOA

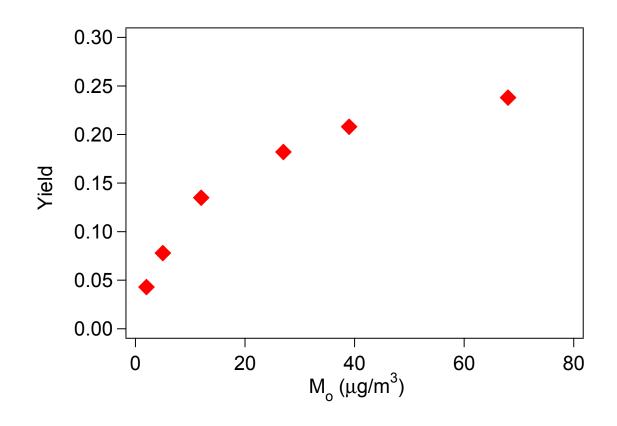

### SOA from Isoprene + NO<sub>3</sub>

Ng, N.L. et al., *Atmos. Chem. Phys. Disc.*, **8**, 3163-3226 (2008)

### **Experimental conditions**

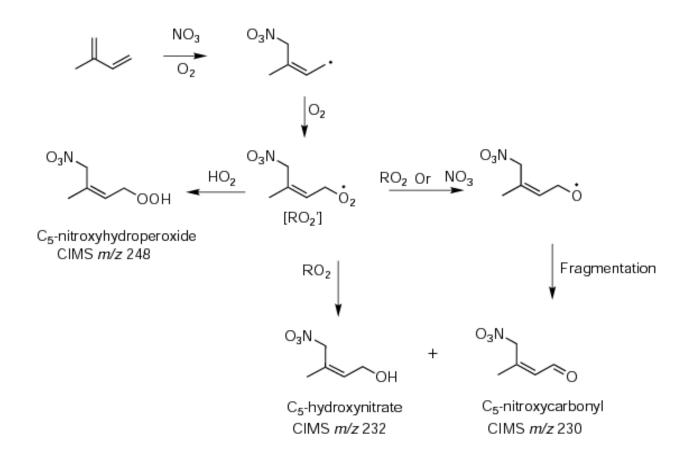

- Ammonium sulfate seed; T~21°C, RH<10%, dark</li>
- N<sub>2</sub>O<sub>5</sub> preparation:
  - Mix 2% ozone in oxygen with pure NO
  - N₂O₅ trapped with a bubbler under dry ice temperature (-70℃)
  - FTIR analysis shows ~95% N<sub>2</sub>O<sub>5</sub>
- SOA Yield experiments:
  - Isoprene injected first and allowed to mix
  - Experiment initiated by injecting ~1 ppm N<sub>2</sub>O<sub>5</sub> into chamber; N<sub>2</sub>O<sub>5</sub> quickly decomposes to form NO<sub>2</sub> and NO<sub>3</sub>
- CIMS experiments:
  - Vary the amount of N<sub>2</sub>O<sub>5</sub> and isoprene injected to study mechanisms of SOA formation
- "Slow Injection" experiments:
  - Isoprene injected first, then inject N<sub>2</sub>O<sub>5</sub> slowly through a 65 L Teflon bag
  - N<sub>2</sub>O<sub>5</sub> injected first, then inject isoprene slowly through 65 L bag

### Secondary organic aerosol (SOA) yield

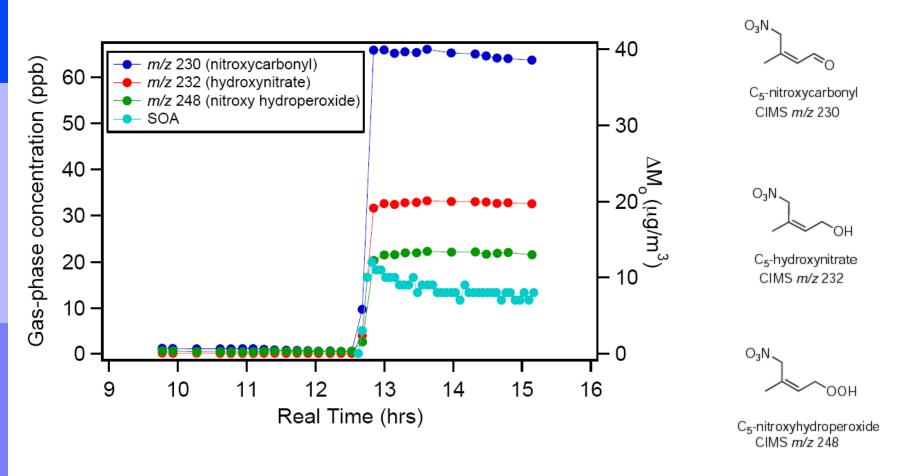

- Isoprene reacted: 18 102 ppb
- SOA density: 1.42 g/cm<sup>3</sup>
- Inorganic nitrate measured by PILS: 1.6 to 2.6 μg/m<sup>3</sup>

### Peroxy Radical Chemistry

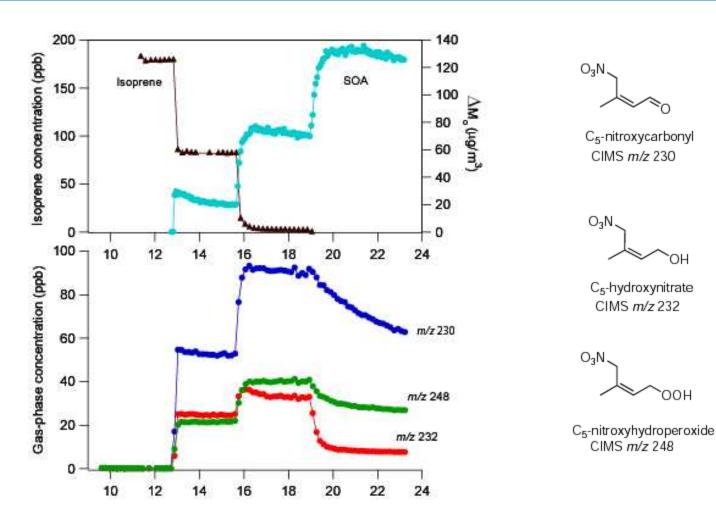

### **Major First-Generation Products**

800 ppb isoprene injected into 130 ppb N<sub>2</sub>O<sub>5</sub>

### **Major First-Generation Products**

OOH

200 ppb isoprene, add 3 pulses of N<sub>2</sub>O<sub>5</sub>

## Conclusion: Important masses for SOA formation

CIMS m/z 377

$$O_3N$$
  $O_3$   $O_4$   $O_5$   $O_7$   $O_8$ 

CIMS m/z 393

### Global predictions of SOA from isoprene + NO<sub>3</sub>

- Two global isoprene emissions are available in GEOS-Chem:
  - GEIA (Global Emission Inventory Activity) [Guenther et al., 1995]
  - MEGAN (Model of Emissions and Gases from Nature) [Guenther et al., 2006]

	GEIA	<u>MEGAN</u>
Isoprene emission (Tg/y)	507	389
Isoprene reacted (Tg/y) by		
Isoprene + OH	407	304
Isoprene + $O_3$	69	62
Isoprene + NO <sub>3</sub>	29	21

Assume 10% SOA yield

2 -3 Tg/y SOA formed

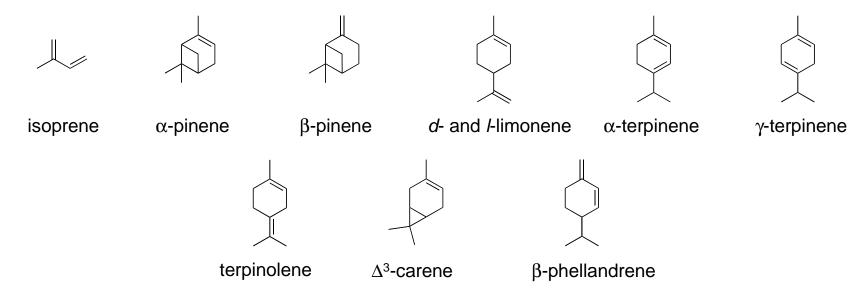

### Organosulfates in Ambient Aerosol

Surratt et al., *ES&T*, **41**, 517-527 (2007)

Surratt et al., J. Phys. Chem., in press (2008)

### Organosulfates in Ambient Aerosol

 Comprehensive laboratory investigation of organosulfate formation from the oxidation of 10 terpenes:

- Reanalyze ambient aerosol collected from the southeastern U.S.
   [Gao et al., JGR, 2006] using more advanced MS techniques
- Compare the laboratory and field MS data to evaluate atmospheric significance

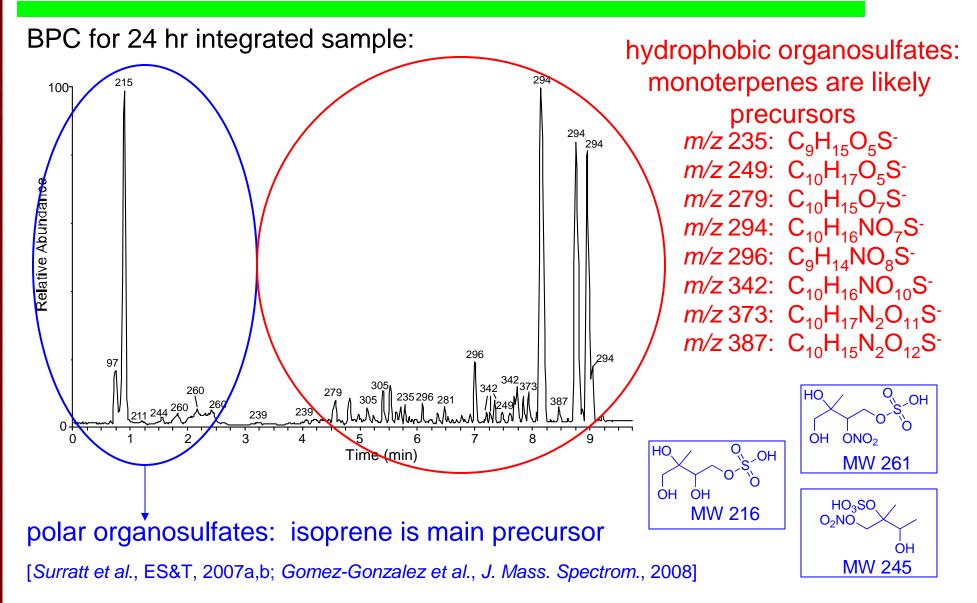

### Atmospheric Significance of Organosulfates

- An upper limit estimate indicates that ~ 30% of the total ambient organic aerosol mass could be in the form of organosulfates
- Organosulfate formation from BVOCs appears to be ubiquitous in ambient aerosol collected from the S.E. USA and Europe
- These compounds are ambient tracers for biogenic SOA formation under acidic conditions
- Both the OH-initiated (in presence/absence NO<sub>x</sub>) and NO<sub>3</sub>-initiated oxidation of BVOCs in the presence of acidified ammonium sulfate seed aerosol leads to organosulfates
- Organosulfates can be regarded as humic-like substances (i.e. multifunctional compounds containing hydroxyl, carboxyl, sulfate, and nitrooxy groups)

### Estimation Method for Organosulfate Contribution

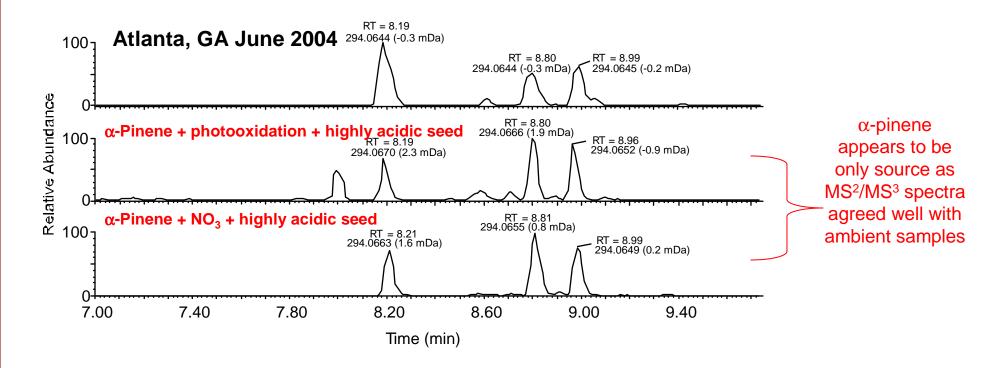

- No authentic and/or suitable surrogate standards are currently available for quantification of characterized organosulfates by UPLC/ESI-TOFMS or HPLC/ESI-linear ITMS
- Contribution of organosulfates to ambient organic aerosol can be derived from the analysis of aerosol samples for total sulfur (measured by x-ray emission techniques - e.g. PIXE or XRF) and water-soluble sulfate (measured by IC)
- Upper limit for sulfur that is associated with organosulfates provided by the subtraction of IC sulfate-sulfur from the PIXE sulfur
- IC sulfate-sulfur and PIXE sulfur data sets were available for 63 PM<sub>10</sub> samples collected from K-puszta in Hungary (organosulfate composition very similar to that of S.E. USA) and were used for our estimate
- Mass percentages of sulfur in some common BSOA organosulfates characterized in this study (e.g. nitrooxy organosulfate of α-pinene with MW 295) were also used in our estimate in order to convert non-sulfate-sulfur into OM

### UPLC/(-)ESI-TOFMS Data: S.E. USA Summer Aerosol

# Source of m/z 294 Nitroxy-Organosulfates ( $C_{10}H_{16}NO_7S^-$ )

- Previously observed in ambient aerosol [Gao et al., 2006; Surratt et al. 2007; linuma et al., 2007]  $\alpha$ -pinene appears to be only precursor
- UPLC/(–)ESI-TOFMS EICs of *m/z* 294:

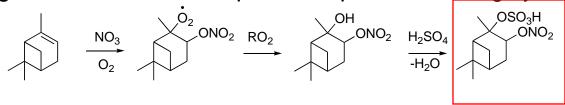

### Proposed Formation of $\alpha$ -Pinene m/z 294 Nitroxy-Organosulfates ( $C_{10}H_{16}NO_7S^-$ )

Photooxidation of  $\alpha$ -pinene in presence of highly acidic seed

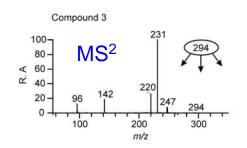

Proposed structure for 3rd isomer observed in UPLC chromatogram

Nighttime-oxidation of  $\alpha$ -pinene in presence of highly acidic seed

[Aschmann et al., JGR, 1998]

Proposed structure for 3rd isomer observed in UPLC chromatogram

*m*/*z* 247: loss of HONO (47 Da)

m/z 231: loss of HNO<sub>3</sub> (63 Da)
